1.0 INTRODUCTION

As part of the Preliminary Feasibility Study in Economic Impact Areas 1 to 10 along South San Francisco Bay Shoreline, this hydraulic analysis was conducted to investigate the flow capacity of nine creeks, located within EIA 1 through EIA10, and the minimum levee/flood wall elevations to provide the 100-year flood protection level. The project site of the South San Francisco Bay Shoreline Study (SSFBSS) is located in the area south of the Dumbarton Bridge at the far southern end of San Francisco Bay. The nine creeks included in the hydraulic analysis are Matadero Creek, Barron Creek, Adobe Creek, Permanente Creek, Stevens Creek, Sunnyvale West Channel, Sunnyvale East Channel, Calabazas Creek and San Tomas Aquino Creek, as shown in Figure 1.

The hydraulic analysis was conducted based on the unsteady HEC-RAS models that were developed by the Corps for the South San Francisco Bay Shoreline Study during the Without-Project (F3 phase) study¹. In total, these nine creeks are covered in five HEC-RAS models. Barron Creek and Adobe Creek are covered in one model, Sunnyvale West Channel, Sunnyvale East Channel, Calabazas Creek and San Tomas Aquino Creek are also included in one model. It is noted that levees and floodwalls were modeled as lateral weirs in these models to allow water to overtop the levees and floodwalls. These lateral weirs were deactivated in our analysis so that the channel flow capacity is evaluated with the full 100-year flow event, not with any reduced flow discharge that may be caused by the insufficient flow capacity of the upstream reaches.

The 100-year flow hydrographs used in our analysis are the same as those incorporated in the Corps' HEC-RAS models. The flow capacity evaluation was conducted with the Mean Higher High Water (MHHW) at the mouth of the creek for the Year 0 (2017) condition, and with MHHW adding future sea level rise projections for the Year 50 (2067) condition. The "low", "intermediate", and "high" SLR rates that were determined based on the USACE guidance² were considered in our evaluation for the Year 50 condition.

Figure 1. Creeks Included in the Hydraulic Analysis

2.0 CHANGE TO HEC-RAS GEOMETRIC DATA

The geometry data files that were included in the Corps' HEC-RAS models¹ for the creeks were reviewed and revised before being used in our hydraulic analysis. The major revisions to the geometry data include the following:

- (1) Replacing the downstream end “dummy” cross sections, which were artificially added in the Corps’ model, with multiple “dummy” sections that can better represent the downstream channel condition. A “dummy” section was typically added in the Corps’ model at a location that is a couple of thousand feet downstream of the last (bayward) surveyed section, by lowering this surveyed section by 10 feet. The purpose of adding this dummy section was to minimize the untruly impact of the downstream boundary condition on the hydraulic parameters computed for the reach of interest. The multiple “dummy” sections added by us were developed based on the NOAA navigational chart and the Google Earth images. It is noted that the model results show that adding these dummy sections has negligible or no impact to the computed 100-year water surface elevations in the reaches of interest.
- (2) Deactivating the lateral structures (weirs) along the creeks so no water will leave the channel even when the water level is higher than the levees and channel banks. The purpose is to evaluate the channel flow capacity with the full 100-year flow event, not with any reduced flow discharge that may be caused by the insufficient flow capacity of the upstream reaches. In other words, our hydraulic analysis is to predict the water levels in the channel after future levee, floodwall, and/or channel improvements.
- (3) Per discussion with the District, all the floodplain areas, which are outside of levees, floodwalls, and channel banks, are assumed to be completely blocked without conveying water. All the water is conveyed within the main channel, which is the channel within the levee/floodwalls, or between the top of banks for incised channels. The purpose is to predict the water level in the channel after future levee and floodwall improvements. This was done by using the “Unsteady Encroachment” approach in the HEC-RAS model combined with removal of some data points in the floodplain areas for a few cross sections.

The geometric coverage of the HEC-RAS model is shown in Figure 2 for Matadero Creek, in Figure 3 for Barron and Adobe Creeks, in Figure 4 per Permanente Creek, in Figure 5 for Stevens Creek, and in Figure 6 for Sunnyvale West Channel, Sunnyvale East Channel, Calabazas Creek, San Tomas Aquino Creek, and Guadalupe Slough.

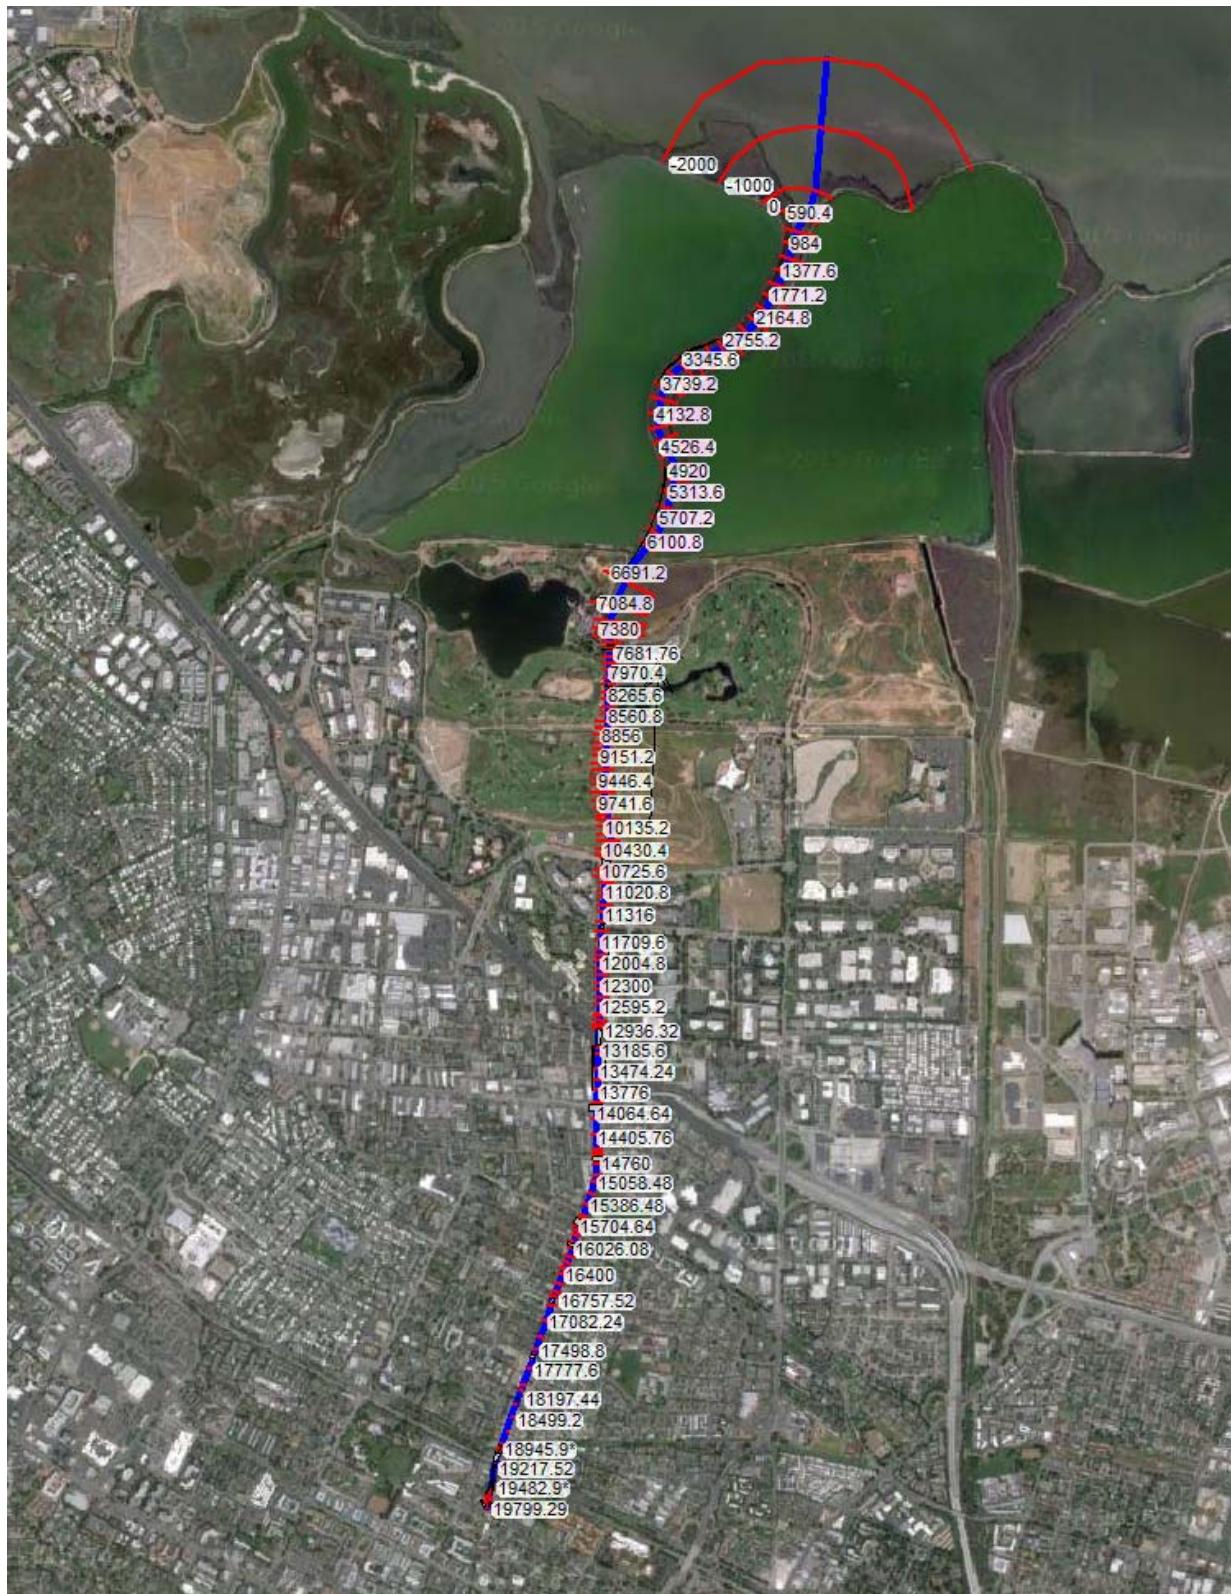

Figure 4. HEC-RAS Model Coverage for Permanente Creek

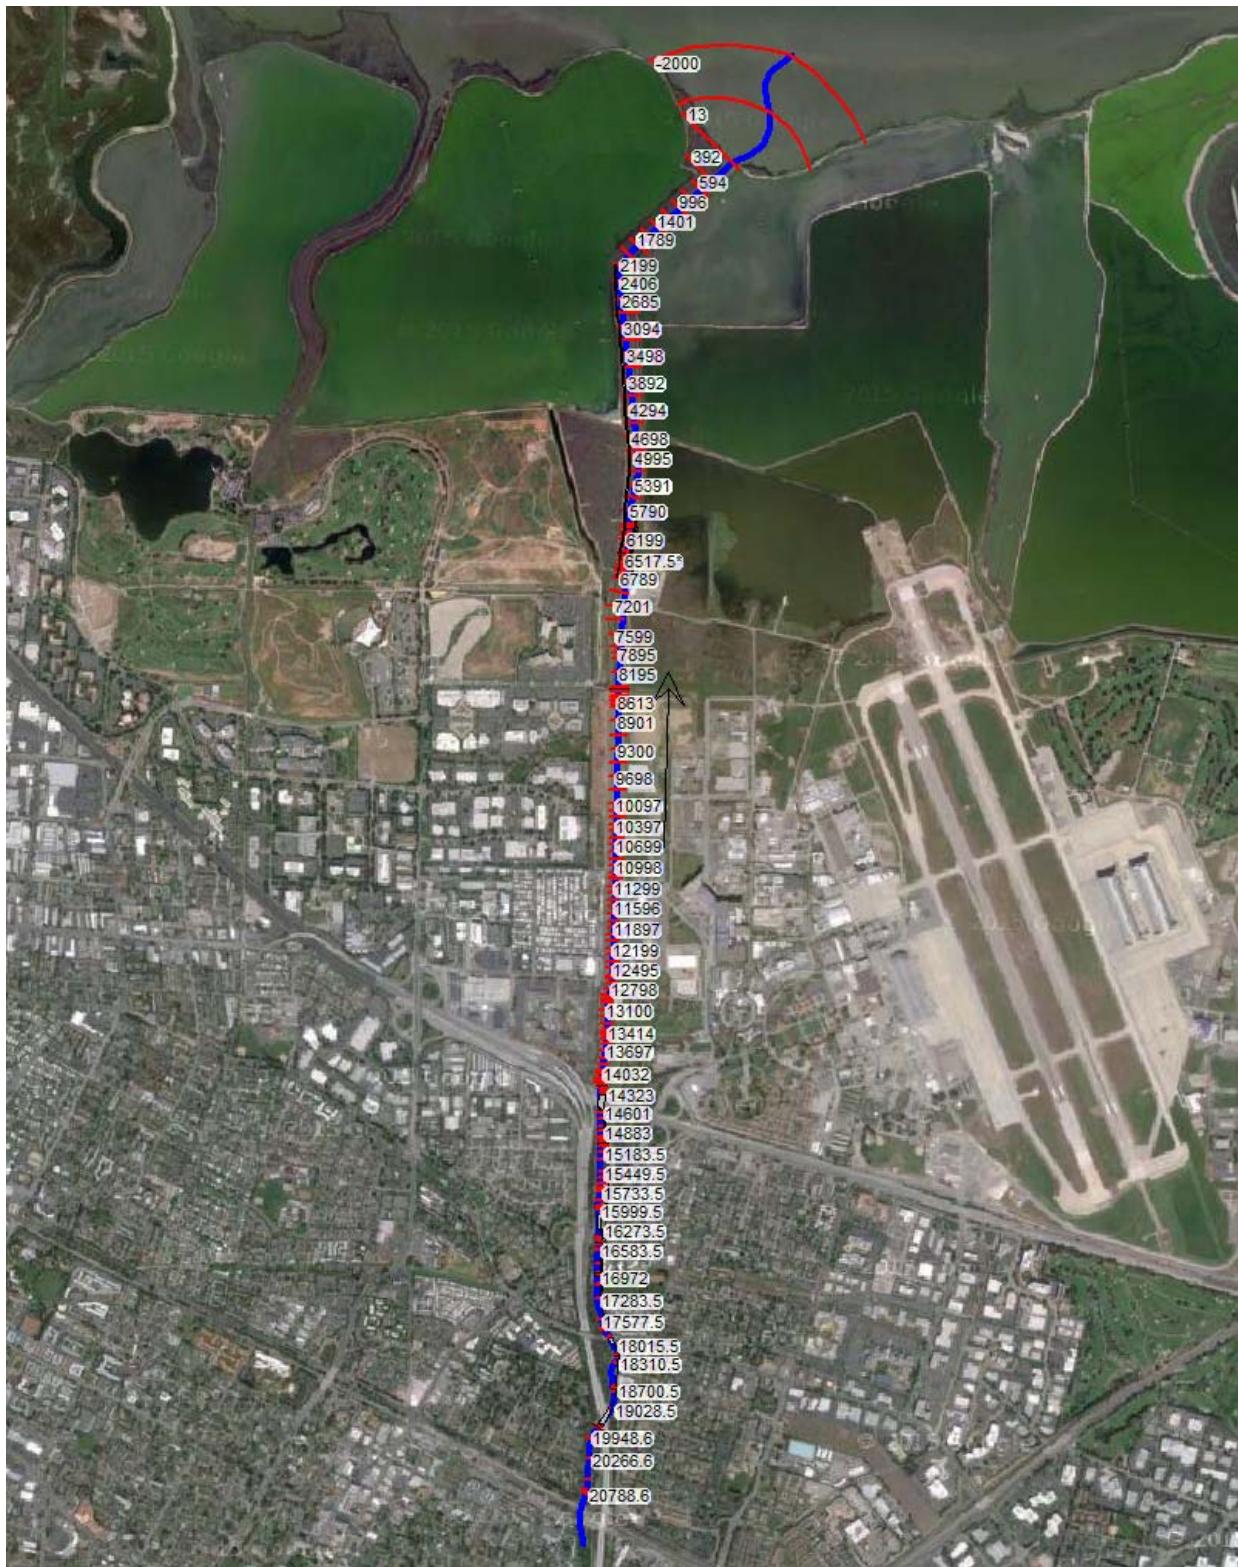

Figure 5. HEC-RAS Model Coverage for Stevens Creek

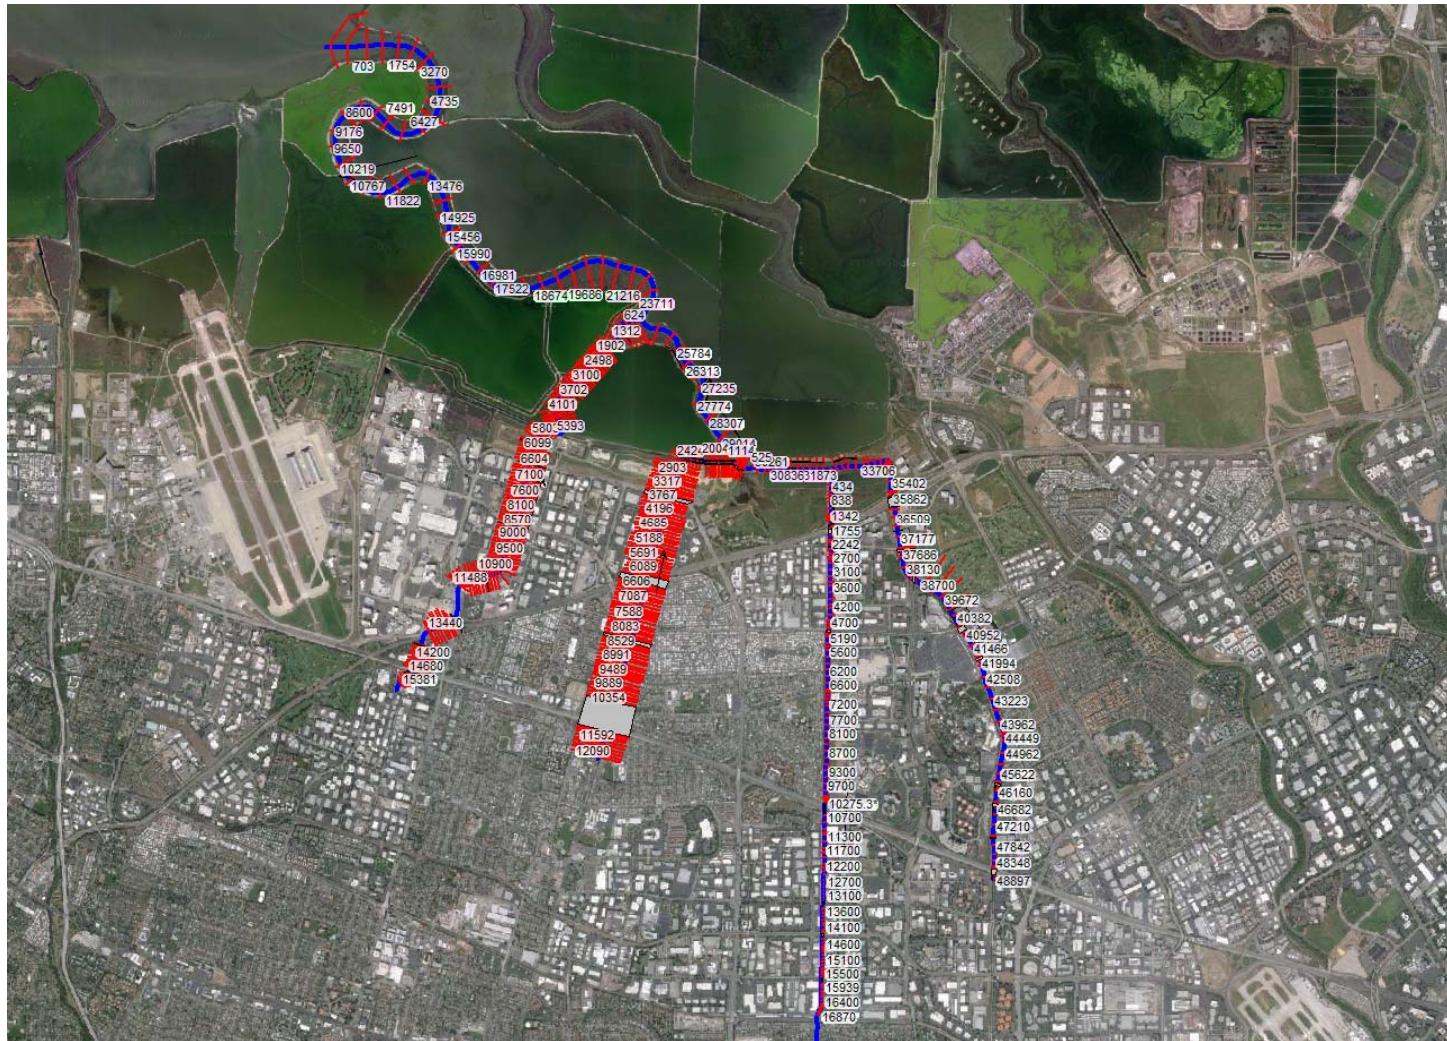

Figure 6. HEC-RAS Model Coverage for Sunnyvale West Channel, Sunnyvale East Channel, Calabazas Creek, and San Tomas Aquino Creek

3.0 HEC-RAS BOUNDARY CONDITIONS

The boundary conditions for the unsteady HEC-RAS model include the water surface elevation at the downstream boundary and the flow hydrographs at the upstream boundary and at the flow change locations along the channel, if any. Our hydraulic capacity analysis was conducted based on the Mean Higher High Water (MHHW) at the river mouth, adding various sea level rise (SLR) projects, together with the 100-year flow hydrographs that were included in the Corps' HEC-RAS models.

3.1 Downstream Water Surface Elevations

MHHW for the tidal epoch 1983-2001 was listed in Table 7 of USACE (2014) report³. It was determined to be +7.64 feet, NAVD 88 for Coyote Creek Station, NOAA ID 9414575. The future SLR starting from 1992 (mid-point of the 1983-2001 epoch) was computed using USACE (2011) guidance². The SLR was estimated to be 0.17 feet from 1992 to Year 0 (2017), and 0.51 feet, 1.01 feet, and 2.59 feet between 1992 and Year 50 (2067) for the USACE “low”, “intermediate”, and “high” SLR rates, respectively. MHHW adding these corresponding SLRs, as summarized in Table 1, was assigned as the downstream (Bay) water level condition for the HEC-RAS models.

3.2 Flow Hydrographs

The 100-year flow hydrographs that were included in the Corps' HEC-RAS models were directly used in our hydraulic analysis. These hydrology data sets were discussed in Chapter 7 of USACE (2013) report for the riverine hydraulic analysis. As examples, the 100-year flow hydrographs are shown in Figure 7 through Figure 11 for the modeled upstream boundaries of the nine creeks, respectively.

It is noted that the upstream channel capacities (reductions) were taken into account in USACE's (2013) hydraulic analysis for Permanente Creek and San Tomas Aquino. The reduction in flow on Permanente Creek is due to capacity limitations from Park Drive to Mountain View Road Downstream of Hale Creek. The reduction in capacity is documented in the SCVWD report, *Permanente Creek Watershed Planning Study, Project Background/Problem Definition Report, February 2004*. Flow leaves the channel in this area reducing the amount of flow downstream to 635 cfs at Villa Street, the SSFBSS study limits. On San Tomas Aquino a restriction is located at San Tomas Expressway limiting the flow to Hwy 101 to 7100 cfs. The restriction is documented in the SCVWD report, *San Tomas Creek, Planning Study, Route 237 to Highway 101, August 1995 and the San Tomas Aquino Creek*

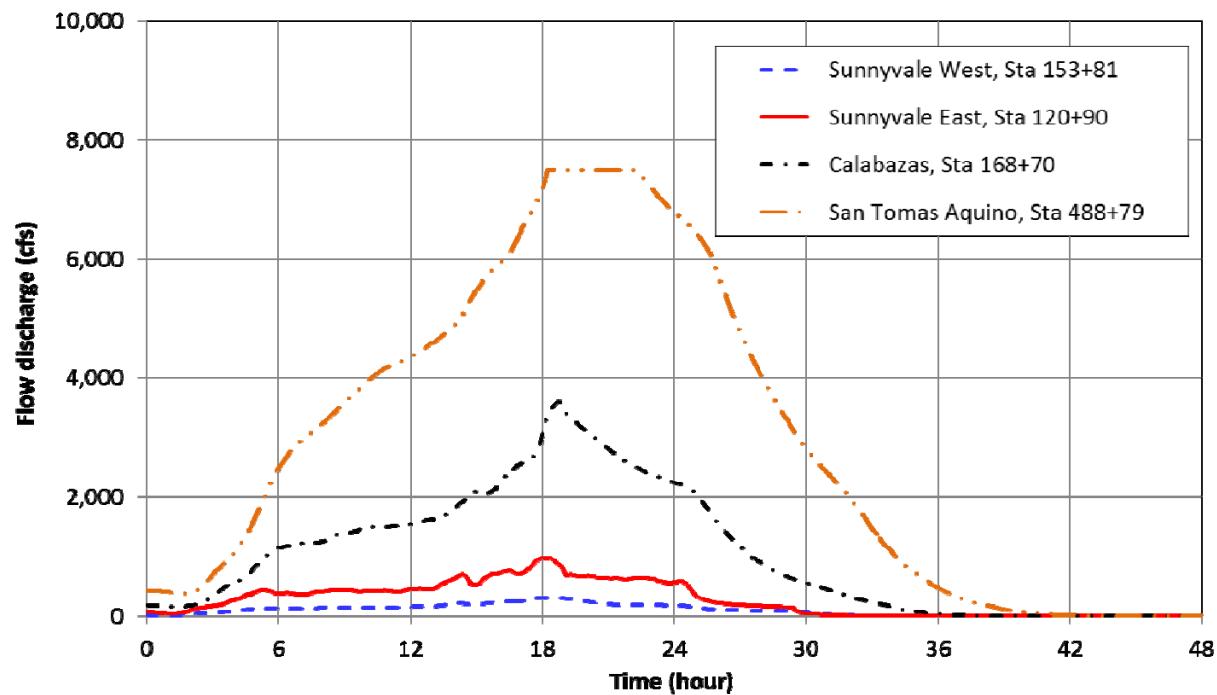

Figure 11. 100-Year Flow Hydrographs at Upstream Boundaries for Sunnyvale West Channel, Sunnyvale East Channel, Calabazas Creek, and San Tomas Aquino Creek

4.0 COMPUTED 100-YEAR WATER SURFACE ELEVATIONS

Four runs were conducted for each HEC-RAS model: one run is for the Year 0 condition, and three runs for the Year 50 condition with three SLR projections, respectively. The computed maximum water surface profile during the 100-year flow event was compared to the channel bank top elevation to determine if the channel meets the 100-year protection criteria. If the channel is protected by a levee or floodwall, the crest elevation of the levee or floodwall is defined as the bank top elevation. For incised channel, channel bank top is defined as the intersection of the channel side slope with the ground that is approximately flat. It is noted that the channel bank top elevations were determined based on the channel cross sections that were included in the Corps' HEC-RAS model, and thus the accuracy of the bank top elevations depends on the accuracy of these cross sections. The results for each creek are summarized as follows.

Matadero Creek

The computed 100-year water surface profiles for the Matadero Creek, compared to the levee/floodwall elevations, are shown in Figure 12 through Figure 15 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 2. It is noted that no free board is included in the analysis, and the required minimum channel bank top elevations are defined as the same as the computed 100-year water surface elevations. If the required channel bank elevations are higher than the existing bank elevations, they are marked in red color in Table 2. The channel flow capacity is summarized as follows.

- The 100-year water surface elevations exceed the levee/floodwall elevations in the reach between the Park Blvd. Bridge and the Lambert Avenue Bridge.
- The impact of the SLR on the channel water levels is limited to the lower reach of the channel. The 100-year water levels show no difference between the Year 0 condition and the Year 50 condition for the reach upstream of the Ross Way Bridge.

Barron Creek

The computed 100-year water surface profiles for the modeled reach of the Barron Creek, compared to the levee/floodwall elevations, are shown in Figure 16 through Figure 19 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 3. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. It is noted that only the lower reach of Barron Creek, which is from its confluence with Adobe Creek to approximately 900 feet upstream of the Louis Road Bridge, was included in the Corp's unsteady HEC-RAS model for this creek. As a result, our hydraulic analysis was also limited for this lower reach. The channel flow capacity is summarized as follows.

- The reach downstream of the Louis Road Bridge has the flow capacity for the 100-year flow event for both the Year 0 condition and the Year 50 condition with various SLR projects.
- The reach upstream of the Louis Road Bridge has the flow capacity for the Year 0 condition and for the Year 50 condition with the “low” and “intermediate” SLR scenarios. However, the 100-year water levels for the Year 50 condition with the “high” SLR projection will exceed the levee/flood wall elevations.

Adobe Creek

The computed 100-year water surface profiles for the Adobe Creek, compared to the levee/floodwall elevations, are shown in Figure 20 through Figure 23 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 4. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. The channel flow capacity is summarized as follows.

- Adobe Creek does not have the 100-year flow capacity in the reach approximately between the Louis Road Bridge and the Charleston Road Bridge, and in a short reach of incised channel upstream of a inline structure at Station 229+47 (upstream of the SPRR and Alma Street Bridge). This is true for both the Year 0 condition and the Year 50 condition with various SLR projections.
- The reach between the Meadow Drive Bridge and the Louis Road Bridge will not have the 100-year flow capacity for the Year 50 condition with the “high” SLR projection.

Permanente Creek

The computed 100-year water surface profiles for the Permanente Creek, compared to the levee/floodwall elevations, are shown in Figure 24 through Figure 27 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 5. Overall, Permanente Creek is able to provide 100-year flood protection except for some locations in the lower reach that passes through the salt ponds.

Stevens Creek

The computed 100-year water surface profiles for the Stevens Creek, compared to the levee/floodwall elevations, are shown in Figure 28 through Figure 31 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 6. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. The channel flow capacity is summarized as follows.

- Stevens Creek does not have the 100-year flow capacity in the reach that is approximately between the Hwy 101 Bridge and the Highway 85 Bridge.
- Stevens Creek does not have the 100-year flow capacity in the lower reach that passes through the salt ponds.
- SLR has negligible impact on the 100-year water levels for the reach included in the hydraulic analysis.

Sunnyvale West Channel

The computed 100-year water surface profiles for the Sunnyvale West Channel, compared to the levee/floodwall elevations, are shown in Figure 32 through Figure 35 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 7. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. The channel flow capacity is summarized as follows.

- Sunnyvale West Channel has the 100-year flow capacity for the reach that is upstream of the salt ponds.
- The lower reach of Sunnyvale West Channel that passes through the salt ponds does not have 100-year flow capacity at multiple locations. This is particularly true for the left bank, when facing downstream.

Sunnyvale East Channel

The computed 100-year water surface profiles for the Sunnyvale East Channel, compared to the levee/floodwall elevations, are shown in Figure 36 through Figure 39 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 8. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. Sunnyvale East Channel has the 100-year flow capacity for the floodwall/levee protected reach that is approximately upstream of Station 25+00. The downstream reach without floodwall/levee does not have the 100-year flow capacity.

Calabazas Creek

The computed 100-year water surface profiles for the Calabazas Creek, compared to the levee/floodwall elevations, are shown in Figure 40 through Figure 43 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 9. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. Calabazas Creek generally has the 100-

year flow capacity except for the right bank of the lower reach that is downstream of the Bay Trail crossing.

San Tomas Aquino Creek

The computed 100-year water surface profiles for the San Tomas Aquino Creek, compared to the levee/floodwall elevations, are shown in Figure 20 through Figure 23 for the Year 0 and the Year 50 conditions, respectively. The required minimum channel bank top elevations to provide the 100-year protection, compared to the existing channel bank top elevations, are listed in Table 10. If the required minimum channel bank top elevations are higher than the existing bank elevations, they are marked in red color in this table. San Tomas Aquino Creek has the 100-year flow capacity except for the lower reach downstream of the Bay Trail crossing.

Note 1. The floodwall elevations as coded into the Corps 2013 HEC-RAS model were used for the reach downstream of Hwy 101 bridge, between station 101+54 downstream to Station 24+24. Those floodwall elevations were very preliminary (and sometimes set simply high enough to contain the flow). The correct design floodwall elevations can be obtained from SCVWD by request to the Sunnyvale East and West Channels flood protection project.

**Table 9. Required Bank Top Elevations for Providing the 100-Year Flood Protection
(Calabazas Creek)**

River Station	Channel bottom elevation (ft, NAVD88)	Existing bank top elevation (ft, NAVD88)		Required minimum bank top elevation (ft, NAVD88)
